

Chem 150, Spring 2015

Unit 1 - Molecular Structures

## 3.1 Covalent Bonds and the Octet Rule

- Group 8A elements are called Noble Gases and do not normally form chemical compounds. All of these elements also have a full valence shell, which leads to stability
- Representative elements tend to form compounds such that they fill their valence shells (octet rule).
- Known as the octet rule because this normally results in compounds in which each atom had 8 electrons in its most outer shell.

# Lewis Structures and Molecules

- Fluorine has 7 valence electrons, and is found as  $F_2$ . In this form, both elements have a share in 8 electrons.
- Lewis structures can be used to represent these **molecules**.

# Bonds

- A **chemical bond** occurs when two atoms are attracted enough to each other to stay together.
- A **covalent bond** occurs when electrons are shared between two atoms.
- A pair of shared electrons is known as a **bonding electron pair**.
- **Lone pairs** or **non-bonding pairs** of electrons are the electrons not involved in the covalent bond.

# Try It!

## Question:

Draw the Lewis dot structure for a molecule that contains one chlorine atom (Cl) and one fluorine (F) atom.

# Atoms, Molecules and Compounds

- A group of two or more atoms (identical or different) is a **molecule**.
- A combination of two or more different elements is a **compound**.
- All compounds are molecules but not all molecules (like  $\text{H}_2$ ,  $\text{F}_2$ , etc) are compounds.

Neon is an **element**,  
and is made up of  
Ne **atoms**.

Fluorine is an  
**element**, and is  
made up of  $\text{F}_2$   
**molecules**.

Chlorine monofluoride  
is a **compound**, and is  
made up of  $\text{ClF}$   
**molecules**.

# Hydrogen

- Hydrogen atoms need only one electron to fill the valence shell to achieve the electron arrangement of Helium.

# Try It!

## Question:

Draw the Lewis dot structure for a molecule that contains one oxygen atom (O) and two hydrogen (H) atoms.

# Covalent Bonds for All Representative Elements

**TABLE 3.1** Covalent Bond Formation in Groups 4A Through 8A

	Group 4A	Group 5A	Group 6A	Group 7A	Group 8A
Number of Valence Electrons	4	5	6	7	8
Number of Empty Spaces in the Valence Shell	4	3	2	1	0
Number of Covalent Bonds Formed	4	3	2	1	0
Example of a Typical Molecule	$\begin{array}{c} \text{H} \\   \\ \text{H}:\text{C}:\text{H} \\   \\ \text{H} \end{array}$ Methane	$\begin{array}{c} \text{H}:\ddot{\text{N}}:\text{H} \\   \\ \text{H} \end{array}$ Ammonia	$\text{H}:\ddot{\text{O}}:\text{H}$ Water	$\text{H}:\ddot{\text{F}}:$ Hydrogen fluoride	These elements do not form molecules.

© Cengage Learning

Elements with 5 or more empty spaces rarely form covalent bonds to fill their empty valence shell.

# Try It!

## Question:

Draw the Lewis dot structure for a molecule that contains two oxygen atoms (O).

## 3.2 Double and Triple Bonds

- One shared pair of electrons (2 total electrons) is a **single bond**.
- **Double bonds** form when atoms share two pairs of electrons (4 total electrons).

- **Triple bonds** form when atoms share three pairs of electrons (6 total electrons).
- Any atom that can form at least 2 bonds can form a double bond and any atom that can form at least 3 bonds can form a triple bond.

## Question:

Hydrogen cyanide is a deadly gas, which halts cellular respiration. Draw the Lewis dot structure for hydrogen cyanide.

# Bonding Patterns for Electrically Neutral Atoms

**TABLE 3.2** Bonding Patterns for Electrically Neutral Atoms

Group Number	Normal Number of Covalent Bonds	Possible Bonding Patterns	Examples
4A	4	$\begin{array}{c}   \\ -X- \\   \end{array}$ $\begin{array}{c} =X- \\   \end{array}$ $\begin{array}{c} \equiv X- \end{array}$	$\begin{array}{c} H \\   \\ H-C-H \\   \\ H \end{array}$ $\begin{array}{c} \ddot{O}=C-H \\   \\ H \end{array}$ $\begin{array}{c} :N\equiv C-H \end{array}$
5A	3	$\begin{array}{c} \ddot{X} \\ - \\   \end{array}$ $\begin{array}{c} =\ddot{X}- \\ \end{array}$ $\begin{array}{c} \equiv X: \end{array}$	$\begin{array}{c} H-\ddot{N}-H \\   \\ H \end{array}$ $\begin{array}{c} \ddot{O}=\ddot{N}-H \end{array}$ $\begin{array}{c} :N\equiv N: \end{array}$
6A	2	$\begin{array}{c} \ddot{X} \\ - \\ \ddot{X} \end{array}$ $\begin{array}{c} =\ddot{X} \end{array}$	$\begin{array}{c} H-\ddot{O}-H \end{array}$ $\begin{array}{c} \ddot{O}=\ddot{O} \end{array}$
7A	1	$\begin{array}{c} \ddot{X}: \end{array}$	$\begin{array}{c} :\ddot{F}-\ddot{F}: \end{array}$

# Bonding Patterns for Electrically Neutral Atoms

There are some exceptions, including non-metals in the third period and higher can violate the octet rule by sharing in more than 8 electrons.

## 3.3 Electronegativity and Polar Bonds

- Atoms of different elements can form **polar covalent bonds**.
  - Atoms of some elements are able to attract electrons in a bond stronger than others.
  - Polar bonds occur when electrons are shared unevenly.

Fluorine attracts the electrons more than hydrogen in HF, so fluorine is partially negative and hydrogen is partially positive.

# Nonpolar Covalent Bonds

- Two identical atoms have equal attraction to electrons in a bond, and therefore share them equally.
- This results in the formation of a **nonpolar covalent bond** in which atoms are not charged.

In F<sub>2</sub>, each atom attracts the electrons equally, so neither atom is charged.

F<sub>2</sub> has a **nonpolar covalent bond**.

# Electronegativity

- **Electronegativity** measures the attraction of an element for electrons.
  - High electronegativity means there is a strong attraction
- Electronegativity increases from left to right and from bottom to top of the periodic table.

# Electronegativity

- **Electronegativity** measures the attraction of an element for electrons.

- High attraction

- Electronegativity from bottom-left to top-right

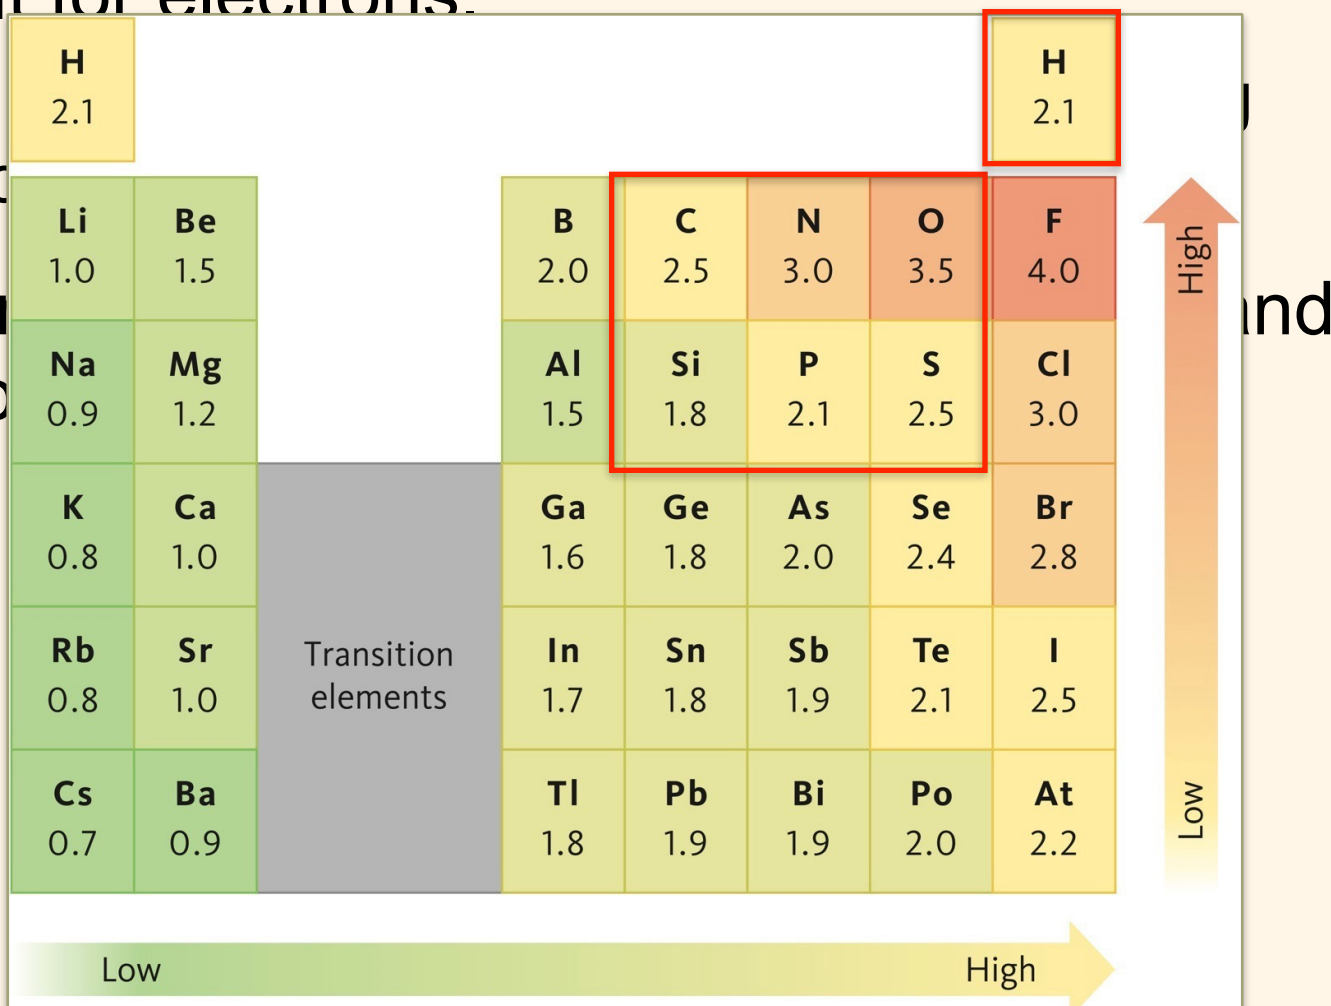

# Electronegativity

- **Electronegativity** measures the attraction of an element for electrons.

- High attraction

- Electronegativity from bottom-left to top-right

# Electronegativity

- **Electronegativity** measures the attraction of an element for electrons.
  - High electronegativity means there is a strong attraction
- Electronegativity increases from left to right and from bottom to top of the periodic table.

# Try It!

## Question:

Draw the Lewis dot structure for carbon monoxide and predict whether or not it is a polar molecule.

## 3.8 Polyatomic Ions

- Ions can be **monatomic**, such as  $\text{Na}^+$  or  $\text{Fe}^{2+}$  or  $\text{Cl}^-$ .
  - For main group, or representative elements, the charge can be predicted from their location on the periodic table.
- Polyatomic ions are ions that are made up of more than one atom, which are covalently bonded together.

Example:  $\text{NaOH}$  consists of  $\text{Na}^+$  and  $\text{OH}^-$ .  $\text{OH}^-$ , hydroxide ion, is a polyatomic ion.

# Example: NaOH

Example: NaOH comprises  $\text{Na}^+$  and  $\text{OH}^-$ .  $\text{OH}^-$ , an hydroxide ion, is a polyatomic ion.

First, hydrogen and oxygen share electrons ...

... to form a covalent bond.

Then sodium gives up an electron to the OH group ...

... to form a pair of ions.

# Common Polyatomic Ions

**TABLE 3.10** Formulas and Names of Common Polyatomic Ions

Formula	Name	Example of a Compound That Contains This Ion
$\text{NH}_4^+$	Ammonium	$\text{NH}_4\text{Cl}$ (ammonium chloride: sal ammoniac)
$\text{OH}^-$	Hydroxide	$\text{Mg}(\text{OH})_2$ (magnesium hydroxide: milk of magnesia)
$\text{NO}_3^-$	Nitrate	$\text{KNO}_3$ (potassium nitrate: saltpeter)
$\text{CO}_3^{2-}$	Carbonate	$\text{CaCO}_3$ (calcium carbonate: chalk)
$\text{SO}_4^{2-}$	Sulfate	$\text{MgSO}_4$ (magnesium sulfate: Epsom salt)
$\text{PO}_4^{3-}$	Phosphate	$\text{Fe}_3(\text{PO}_4)_2$ (iron(II) phosphate: ferrous phosphate)
$\text{HCO}_3^-$	Hydrogen carbonate (or bicarbonate)	$\text{NaHCO}_3$ (sodium hydrogen carbonate: sodium bicarbonate, baking soda)

# Polyatomic Ions in Compounds

- Compounds with polyatomic ions should be balanced in the same way as compounds with monatomic ions.
- Polyatomic ions are treated as a unit. If there is more than one polyatomic ion, parentheses are used.

Example: What is the formula for calcium nitrate?

$\text{Ca}^{2+}$  and  $\text{NO}_3^-$ . We need 2  $\text{NO}_3^-$  to balance the  $\text{Ca}^{2+}$ , so we use parenthesis.

## 3.9 Recognizing Ionic and Molecular Compounds

- Ionic compounds typically contain a metallic element
  - $\text{CaO}$ ,  $\text{Fe}(\text{NO}_3)_3$ ,  $\text{NaC}_2\text{H}_3\text{O}_2$
- Molecular (covalent) compounds typically contain only non-metals
  - $\text{CO}_2$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{CH}_3\text{OH}$ ,  $\text{C}_3\text{H}_5(\text{NO}_3)_3$
- $\text{NH}_4^+$  is an ion, so compounds that contain  $\text{NH}_4^+$  are ionic
  - $\text{NH}_4\text{Cl}$ ,  $(\text{NH}_4)_3\text{PO}_4$

# Ionic and Molecular Compounds

- Hydrogen containing compounds, like HCl or  $\text{H}_2\text{SO}_4$ , are molecular structures with covalent bonds, because hydrogen is a non-metal.
- Naming conventions differ for ionic and covalent compounds, so it is important to distinguish them.
- For example:
  - $\text{AlCl}_3$  is ionic- aluminum chloride
  - $\text{PCl}_3$  is molecular- phosphorous trichloride

# Ionic and Molecular Compounds

TABLE 3.11 A Comparison of Ionic Compounds Containing Monatomic and Polyatomic Ions				
CATION	COMPOUNDS FORMED WITH -1 IONS		COMPOUNDS FORMED WITH -2 IONS	
	(Cl <sup>-</sup> and NO <sub>3</sub> <sup>-</sup> )		(S <sup>2-</sup> and CO <sub>3</sub> <sup>2-</sup> )	
Na <sup>+</sup>	NaCl (sodium chloride)	NaNO <sub>3</sub> (sodium nitrate)	Na <sub>2</sub> S (sodium sulfide)	Na <sub>2</sub> CO <sub>3</sub> (sodium carbonate)
Mg <sup>2+</sup>	MgCl <sub>2</sub> (magnesium chloride)	Mg(NO <sub>3</sub> ) <sub>2</sub> (magnesium nitrate)	MgS (magnesium sulfide)	MgCO <sub>3</sub> (magnesium carbonate)
Al <sup>3+</sup>	AlCl <sub>3</sub> (aluminum chloride)	Al(NO <sub>3</sub> ) <sub>3</sub> (aluminum nitrate)	Al <sub>2</sub> S <sub>3</sub> (aluminum sulfide)	Al <sub>2</sub> (CO <sub>3</sub> ) <sub>3</sub> (aluminum carbonate)

# Chapter 3—Key Health Science Notes

- In many of the health sciences, you will ***continually*** learn about the naming of medications, both the generic and brand names
  - In some medications that contain ions, the positive ion is named after the negative ion, for example:
    - The chemical name of the cholesterol-lowering medication Lipitor<sup>®</sup> is generally written *atorvastatin calcium*, although the calcium is a +2 ion
